Published 2011

This report describes key findings from the Smoking Toolkit Study (STS) relevant to development of tobacco control policy for the years 2007 to 2010. The STS is a continuing series of monthly surveys of representative sample of the population of England aged 16+. Each monthly wave is followed up for 6 months by means of a postal survey. Full details of the study methods are described elsewhere. This document focuses on top level study findings relating to smokers and recent ex-smokers. It does not stratify findings by sociodemographic variables. Neither does it address issues relating to harm reduction. A number of papers have been published from the study that include analyses relating to such stratification and to harm reduction.

Smoking prevalence

Cigarette smoking prevalence declined from 24.1% in 2007 to 21.4% in 2010 (Figure 1). Prevalence of smoking of any tobacco product in 2010 was 21.9%. Prevalence of any smoking within the past year was 23.3%. There has been little change in smoking prevalence since 2008.

Cigarette consumption and spending on tobacco products

The average daily cigarette consumption has declined from 14.5 cigs per day in 2007 to 13.1 in 2010 (p<0.001 by analysis of variance, Figure 2). There was a sharper fall in consumption of manufactured cigarettes and a rise in the consumption of hand-rolled cigarettes (p<0.001 by analysis of variance in both cases).
Figure 2: Mean daily consumption of different types of cigarette. Base: all current cigarette smokers, N=8,650(2007), 6,446(2008), 6,827(2009), 6,376(2010). Samples sizes are reduced for manufactured and hand-rolled cigarettes because of missing values. This also leads to these not adding exactly to the total number of cigarettes smoked.

The average price paid per 20 cigarettes smoked in 2007 increased from £1.86 for hand rolled and £4.82 for manufactured to £2.08 for hand-rolled and £5.24 for manufactured in 2010. The overall price per cigarette also rose from £3.83 to £4.00 (p<0.0001 for the increase in all cases by linear regression, Figure 3). The increase in the overall price per cigarette was reduced by switching from manufactured to hand-rolled (see Figure 2). This, together with the overall drop in consumption, meant that the weekly cost of smoking remained static from 2008 through 2010 (Figure 4).

Figure 3: Amount spent per 20 cigarettes by type of cigarette and year. Base: All cigarette smokers. N=4,043(2008), 2,238(2009), 2,164(2010)2238(2010). Questions about price paid were not asked in all waves and some missing data for hand-rolled and manufactured cigarettes questions.
The consistency of the information provided by respondents on price paid per week on smoking and numbers of manufactured and hand-rolled cigarettes was assessed by examining the variance accounted for ($R^2$) in each year when the weekly spending was regressed on to the numbers of different types of cigarette smoked, forcing the regression through the origin. The figures were 0.83, 0.86 and 0.83 for 2008, 2009 and 2010 respectively, showing a very high level of consistency between the different types of information.

**Motivation to stop smoking**

Motivation to quit is strongly predictive of quit attempts in the subsequent 3 and 6 months ($p<0.0001$ by chi-squared test for both 3- and 6-month follow up, Figure 5).

![Figure 5](image_url)  
*Figure 5: Association between ratings of motivation to quit at baseline and reports of quit attempts between baseline and 3-month follow up and 6-month follow up. Base: Current cigarette smokers at baseline who were successfully followed up; N=1708(3 month), 2088(6 month)*
The proportion of smokers not wanting to quit has increased from 27.2% in 2008 to 33.6% in 2010. The decrease has been mainly in the percentage who really want to quit but do not know when (p<0.0001 by chi-squared test for overall change in percentages, Figure 6).

Attempts to stop smoking

The proportion of smokers who tried to quit in the previous 12 months has declined from 42.5% in 2007 to 35.9% in 2010 (p<0.0001 by chi-squared test, Figure 7).
Receipt of advice to stop smoking

Only a minority of smokers recalled having discussed smoking with their GP in the past 12 months in 2010 and only 25.9% recalled having been offered a prescription or advised to see a stop smoking practitioner (Figure 8).

![Figure 8: Percentage of smokers who reported having received advice from their GP on smoking in the past 12 months. Base: 5,801 respondents in 2010 who had smoked in the past 12 months. Data collection began in 2010](image)

Recollection of having been advised to stop smoking by their GP was not associated with a significant increase in reports of having made a quit attempt, but having received an offer of a prescription or recommendation to see a stop smoking advisor (practice nurse or go to the Stop Smoking Service) was associated with a markedly higher proportion of reports of quit attempts (p<0.0001 by chi-squared test, Figure 9).

![Figure 9: Percentage of smokers who reported having made a quit attempt in the past 12 months as a function of advice received from their GP during that time. Base: All respondents who had smoked in the past 12 months, N=21,271](image)
Use of aids to cessation

The proportion of smokers who made at least one quit attempt who used some form of cessation aid increased from 49.1% in 2007 to 53.6% in 2010; the increase was primarily in those who used a prescription with minimal behavioural support (p<0.001 by chi-squared test for the overall change in proportions, Figure 10).

![Figure 10: Percentage of smokers who made at least one quit attempt in the past year who used different aids to cessation. Base: All smokers who reported having made at least one quit attempt in the past 12 months. N=2,534(2007), 1,831(2008), 1,833(2009), 2,068(2010)](image)

![Figure 11: The proportion of smokers who made quit attempts in the past 12 months who used different types of medication. Base: All those who smoked in the past 12 months who made at least one quit attempt in the past 12 months. N=2,533(2007), 1,830(2008), 1,832(2009), 2,068(2010)](image)
There has been an increase in proportion of smokers who make quit attempts who used varenicline from 0.06% in 2007 to 8% in 2010 (p<0.0001 by chi-squared test) with no commensurate fall in the use of prescriptions for other medications (Figure 11).

**Approaches to quitting**

There was a decline in the percentage of quit attempts that were unplanned from 58.1% in 2007 to 48.1% in 2010 (p<0.0001 by chi-squared test, Figure 12). The proportion of quit attempts that involved cutting down gradually remained static at around 40%.

![Unplanned and Gradual Quit Attempts](image)

*Figure 12: Percentage of smokers adopting different approaches to quitting in their most recent quit attempt. Unplanned=made the quit attempt as soon as the decision was taken and did not even wait a day; gradual=made the quit attempt by cutting down first. Base=All those who smoked in the past 12 months who made at least one quit attempt. N=2,525(2007), 1,827(2008), 1,832(2009), 2,054(2009)*

**Success at stopping smoking**

Figure 13 shows the proportion of ever-confirmed-smokers (people who report that they ever smoked for at least a year) who go on to become ex-smokers (not smoked for at least a year), aggregating data from all years of the study. Only 25% achieve ex-smoker status by the age of 35, when they begin to lose significant life-expectancy. Only 55% achieve this by the age of 65.
The proportion of last-year smokers (people who had smoked within the past 12 months) who reported no longer smoking declined from 6.7% in 2007 to 4.8% in 2010 (p<0.001 by chi-squared test, Figure 14). There was also a fall in the proportion who had succeeded given that they made a quit attempt (p=0.02 by chi-squared test).

Aggregating data over all years, a multiple logistic regression analysis was used to assess the predictors of current non-smoking status among those who had attempted to stop within the past 12 months. All predictors were entered simultaneously (giving adjusted odds ratios). Table 1 shows the results.

Table 1: Predictor of success (currently not smoking) of quit attempts made in the previous 12 months by forced entry multiple logistic regression. Base=All respondents who had smoked in the past year and made at least one quit attempt. N=8,551. Routine and manual=social grade C-E; Dependence=ratings of strength of urges smoke (1=no urges-6=extremely strong); Abrupt=tried to quit without cutting down first; Unplanned=tried to quit as soon as made the decision; Rx=prescription with minimal behavioural support, NRT OTC=nicotine replacement therapy bought over the counter.

Success was associated with greater age, non routine and manual occupation, lower dependence, not having tried to quit previously that year, having made the quit attempt more recently, and abrupt rather than gradual cessation. Use of specialist NHS support (which includes medication) was associated with 3.53 times the odds of quitting compared with unaided quit attempts and use of medication on prescription was associated with 1.72 times the odds of quitting. No improvement in success rates could be found for NRT bought over the counter.

A logistic regression analysis was undertaken restricted to respondents who had tried to quit with medication obtained on prescription or provided by the NHS specialist service to determine whether the type of medication used was associated with success rates. It was found that those who used varenicline had 1.48 (95% CI 1.03-2.14) times the odds of success compared with those using NRT after adjusting for all the predictor variables used previously.
